Abstract

We constrain some lepton flavor violating vertices in the context of the two Higgs doublet model type III, assuming that the lightest scalar Higgs mass m_{h^0} is about 115 GeV. Specifically, based on the $g-2$ muon factor and the decay width of $\mu \to e\gamma$, the following quite general bounds are obtained: $7.62 \times 10^{-4} \lesssim \xi^2_{\mu\tau} \lesssim 4.44 \times 10^{-2}$, $\xi^2_{e\tau} \lesssim 2.77 \times 10^{-14}$. Additionally, based on the processes $\tau \to \mu\gamma$, and $\tau \to \mu\mu\mu$, bounds on $\xi_{\tau\tau}$ and $\xi_{\mu\mu}$ are also gotten, such constraints on these parameters still give enough room for either a strong suppression or strong enhancement on the coupling of any Higgs boson to a pair of tau leptons or a pair of muons**.** Furthermore, upper limits on the decay widths of the leptonic decays $\tau \to e\gamma$, and $\tau \to eee$ are calculated, finding them to stay far from the reach of near future experiments.

1 Introduction

It is well known that processes involving Flavor Changing Neutral Currents (FCNC), are severely suppressed by experimental data, despite they seem not to violate any fundamental law of nature. On the other hand, Standard Model (SM) issues are compatible with experimental constraints on FCNC so far, with the remarkable exception of neutrino oscillations. Preliminary measurements of the flux of solar neutrinos [1] yielded a result considerably smaller than the one expected from the standard solar model, from which the possibility of oscillation of neutrinos arose as a possible solution to the neutrino deficit observed [2]. Later on, neutrino oscillations in matter were proposed to explain the deficit confirmed by SuperKamiokande [3]. Additional experiments with solar [4] and atmospheric neutrinos [5] have supported the idea of the oscillations.

On the other hand, this phenomenon implies the existence of mass terms for neutrinos, and the existence of family lepton flavor violation. Both implications lead us in turn to consider the existence of physics beyond the SM, since in the

SM neutrinos are massless and lepton flavor violating mechanisms are absent. Therefore, the increasing evidence on neutrino oscillations motivates the study of models with lepton flavor violation. There are some interesting scenarios in which FCNC and therefore LFV appears naturally. For example, the introduction of new representations of fermions different from doublets produce FCNC by means of the Z-coupling [8]. On the other hand, they could arise at the tree level in the Yukawa sector if a second doublet is added to the SM [9]. Another interesting scenario appears in SUSY theories with R-parity broken [10], because FCNC coming from R-parity violation generates massive neutrinos and neutrino oscillations [11]. FCNC in SUSY theories in the charged lepton sector have been studied as well. For instance, the decays $\mu \to e\gamma$ and $\mu \to 3e$ with polarized muons have been examined in the context of supersymmetric grand unified theories [12].

Moreover, neutrino oscillations have inspired the study of Lepton Flavor Violating (LFV) processes in the neutral leptonic sector. For example, LFV processes in SU(5) SUSY models with right handed neutrinos have been examined based on recent results of neutrino oscillation experiments [15]. On the other hand, ref [16] explores the generation of LFV by using a multi-Higgs doublet model with additional right handed neutrinos for each lepton generation, finding a non-decoupling behavior of some LFV amplitudes respect to the Right handed neutrino masses.

Additionally, experimental search has imposed some upper limits for the branching of many processes involving LFV as in the case of $K_L^0 \to \mu^+ e^-$ [17], $K_L^0 \to \pi^0 \mu^+ e^-$ [18], $K^+ \to \pi^+ \mu^+ e^-$ [19], $\mu^+ \to e^+ \gamma$ [20], $\mu^+ \to e^+ e^+ e^-$ [21] and $\mu^- N \to e^- N$ [22]. As for experimental prospects, muon colliders offer a very appealing alternative because of its potential to test the mixing between the second and third (first) generations by processes like $\mu\mu \to \mu\tau(e\tau)$ mediated by Higgs exchange [6], [23],[24].

Perhaps the simplest framework to look for these rare processes is the Two Higgs Doublet Model (2HDM), which consists of considering the possibility of duplication of the SM Higgs doublet. Owing to the addition of the second doublet, the Yukawa interactions lead naturally to tree level FCNC unless we make additional assumptions. The most common one is the imposition of a discrete symmetry [13] which in turn generates two independent sets of Yukawa interactions known as models type I and II. Notwithstanding, we can still have the possibility of preserving all terms in the Yukawa sector (known as model Type III) and obtain constraints on the matrix elements by experimental data. For example, FCNC at the tree level could be compatible with experiments in certain regions of the parameter space if we consider the exchange of heavy scalar or pseudoscalar Higgs fields [14] or by cancellation of large contributions with opposite sign.

Finally, a very important test of FC vertices in leptons could be provided by the $(g-2)/2$ muon factor (a_μ). Recent measurements of a_μ at BNL [25] have reduced the uncertainty by a factor of two from previous measurements. On the other hand, SM estimations on a_μ come from QED, electroweak, and hadronic contributions [26]; the hadronic ones carry the bulk of the uncertainties. In

particular, the light by light hadron contributions have been recently corrected [27]. From the experimental and SM values of a_μ it is possible to estimate the room for new physics (Δa_μ) available for this observable. Several works constraining LFV processes from previous estimations on Δa_μ have been carried out [28, 29]. In order to constrain such kind of processes, we shall use the following interval for Δa_μ at 95% confidence level (C.L.), reported by [30]

$$9.38 \times 10^{-10} \leq \Delta a_\mu \leq 51.28 \times 10^{-10} \tag{1}$$

In this paper we examine constraints on the Flavor Changing (FC) vertices in the lepton Yukawa sector of the 2HDM type III. Such bounds will be gotten from Δa_μ and the leptonic decays $\mu \to e\gamma$, $\tau \to \mu\gamma$ and $\tau \to \mu\mu\mu$. In addition, we predict upper limits for the decays $\tau \to e\gamma$ and $\tau \to eee$.

2 LFV Processes

The Yukawa interactions in the 2HDM type III, relevant for our purposes are

$$\begin{aligned} -\pounds_Y &= \frac{g}{2M_W}\overline{E}M_E E\left(\cos\alpha H^0 - \sin\alpha h^0\right) + \frac{1}{\sqrt{2}}\overline{E}\xi_E E\left(\sin\alpha H^0 + \cos\alpha h^0\right) \\ &+ \frac{i}{\sqrt{2}}\overline{E}\xi_E\gamma_5 E A^0 + \text{h.c.} \end{aligned} \tag{2}$$

where $H^0(h^0)$ denote the heaviest (lightest) neutral $CP-$even scalar, and A^0 is a $CP-$odd scalar. E refers to the three charged leptons $E \equiv (e,\mu,\tau)^T$ and M_E, ξ_E are the mass matrix and the matrix of flavor changing vertices respectively. Finally, α is the mixing angle in the $CP-$even sector. We are working in the simplest parametrization of the 2HDM type III in which only one of the doublets acquire a Vacuum Expectation Value (VEV) [14].

Now, we write down the expressions for the processes relevant in our analysis. For Δa_μ we shall use the integral expression [31] for the sake of accuracy. The expressions for Δa_μ, are given by

$$\begin{aligned} \Delta a_\mu &= \sum_S I_S + \sum_P I_P \ , \\ I_{S(P)} &= C^2_{S(P)}\frac{m_\mu^2}{8\pi^2}\int_0^1 \frac{x^2\left(1 - x \pm m_\tau/m_\mu\right)}{m_\mu^2 x^2 + \left(m_\tau^2 - m_\mu^2\right)x + M^2_{S(P)}\left(1-x\right)}dx \end{aligned} \tag{3}$$

where $I_{S(P)}$ is an integral involving an Scalar (Pseudoscalar) Higgs boson with mass $M_{S(P)}$, and $C_{S(P)}$ is the corresponding coefficient in the Yukawa Lagrangian (2). On the other hand, the expressions for $\Gamma\left(\tau \to \mu\gamma\right)$, $\Gamma\left(\tau \to e\gamma\right)$ and $\Gamma\left(\mu \to e\gamma\right)$ yield

$$\begin{aligned} \Gamma\left(\tau \to l\gamma\right) &= \xi^2_{l\tau}\frac{G_F\alpha_{em}m_\tau^5}{4\pi^4\sqrt{2}}R\left(m_{H^0}, m_{h^0}, m_{A^0}, \alpha, \xi_{\tau\tau}\right) \ , \\ \Gamma\left(\mu \to e\gamma\right) &= \xi^2_{\mu\tau}\xi^2_{e\tau}\frac{\alpha_{em}m_\tau^4 m_\mu}{16\pi^4}S\left(m_{H^0}, m_{h^0}, m_{A^0}, \alpha, \xi_{\tau\tau}\right) \ . \end{aligned} \tag{4}$$

where $l \equiv e, \mu$ denotes a light charged lepton. In addition, we have defined

$$\begin{aligned} R\left(m_{H^0}, m_{h^0}, m_{A^0}, \alpha, \xi_{\tau\tau}\right) &= \left| \left(m_\tau \sin 2\alpha + \frac{\sqrt[4]{2}\xi_{\tau\tau}\sin^2\alpha}{\sqrt{G_F}} \right) \frac{\ln\left[m_{H^0}/m_\tau\right]}{m_{H^0}^2} \right. \\ &- \left(m_\tau \sin 2\alpha - \frac{\sqrt[4]{2}\xi_{\tau\tau}\cos^2\alpha}{\sqrt{G_F}} \right) \frac{\ln\left[m_{h^0}/m_\tau\right]}{m_{h^0}^2} \\ &- \left. \frac{2\sqrt[4]{2}\xi_{\tau\tau}}{\sqrt{G_F}} \frac{\ln\left[m_{A^0}/m_\tau\right]}{m_{A^0}^2} \right|^2 , \\ S\left(m_{H^0}, m_{h^0}, m_{A^0}, \alpha, \xi_{\tau\tau}\right) &= \left| \sin^2\alpha \frac{\ln\left[m_{H^0}/m_\tau\right]}{m_{H^0}^2} + \cos^2\alpha \frac{\ln\left[m_{h^0}/m_\tau\right]}{m_{h^0}^2} \right. \\ &+ \left. \frac{\ln\left[m_{A^0}/m_\tau\right]}{m_{A^0}^2} \right|^2 . \end{aligned} \tag{5}$$

Finally, the expression for a lepton L going to three leptons of the same flavor l is given by

$$\begin{aligned} \Gamma\left(L \to \overline{l} l l\right) &= \frac{m_L^5}{2048\pi^3} \left[\sin 2\alpha \sqrt{\frac{G_F}{\sqrt{2}}} \left(\frac{1}{m_{H^0}^2} - \frac{1}{m_{h^0}^2} \right) m_l \right. \\ &+ \left. \xi_{ll} \left(\frac{\sin^2\alpha}{m_{H^0}^2} + \frac{\cos^2\alpha}{m_{h^0}^2} - \frac{1}{m_{A^0}^2} \right) \right]^2 . \end{aligned} \tag{6}$$

2.1 Obtaining the bounds

¿From the previous section, the free parameters that we are involved with, are: the three neutral Higgs boson masses $(m_{h^0}, m_{H^0}, m_{A^0})$, the mixing angle α, and some flavor changing vertices ξ_{ij}. Based on the present bounds from LEP2 we shall assume that $m_{h^0} \approx 115$ GeV. In addition, we shall assume that $m_{A^0} \gtrsim m_{h^0}$, both assumptions will be held throughout the document. Now, since we are going to consider plots in the $\xi_{ij} - m_{A^0}$ plane, we should manage to use appropiate values of (m_{H^0}, α) in order to sweep a wide region of parameters. In order to sweep a reasonable set of this couple of parameters we utilize for m_{H^0} values of the order of 115 GeV (light), 300 GeV (intermediate), and very large masses (heavy). As for the angle α, we consider values of $\alpha = 0$ (minimal mixing), $\alpha = \pi/4$ (intermediate mixing), and $\alpha = \pi/2$ (maximal mixing). We can check that all possible combinations of (m_{H^0}, α) could be done by considering five cases 1) when $m_{H^0} \simeq 115$ GeV; 2) when $m_{H^0} \simeq 300$ GeV and $\alpha = \pi/2$; 3) when m_{H^0} is very large and $\alpha = \pi/2$; 4) when $m_{H^0} \simeq 300$ GeV and $\alpha = \pi/4$; 5) when m_{H^0} is very large, and $\alpha = \pi/4$. In all these cases the mass of the pseudoscalar will be considered in the range 115 GeV$\lesssim m_{A^0}$.

The first bounds come from Δa_μ. We use the estimated value of it, given by [30] at 95% C.L. eq. (1). Since Δa_μ in eq. (1) is positive, lower and

	Bounds on $\xi^2_{\mu\tau}$	Bounds on $\xi^2_{e\tau}\xi^2_{\mu\tau}$	Bounds on $\xi^2_{e\tau}$
case 1	$7.62\times10^{-4}\lesssim\xi^2_{\mu\tau}\lesssim 8.31\times10^{-3}$	$\xi^2_{e\tau}\xi^2_{\mu\tau}\lesssim 7.33\times10^{-18}$	$\xi^2_{e\tau}\lesssim 4.82\times10^{-15}$
case 2	$1.29\times10^{-3}\lesssim\xi^2_{\mu\tau}\lesssim 4.42\times10^{-2}$	$\xi^2_{e\tau}\xi^2_{\mu\tau}\lesssim 2.24\times10^{-16}$	$\xi^2_{e\tau}\lesssim 2.77\times10^{-14}$

Table 1: Constraints on the mixing parameters $\xi^2_{\mu\tau}$, $\xi^2_{e\tau}\xi^2_{\mu\tau}$ and $\xi^2_{e\tau}$ for the five cases mentioned in the text. The two former are generated from Δa_μ and $\Gamma(\mu\to e\gamma)$ respectively, while the latter comes from the combination of the lower limit on $\xi^2_{\mu\tau}$ and the upper bound on $\xi^2_{e\tau}\xi^2_{\mu\tau}$.

upper bounds for the FC vertex $\xi_{\mu\tau}$ can be gotten at 95% C.L. The results are indicated in table (1) column 1. The lower bounds in each case are obtained when $m_{A^0}\approx 115$ GeV, and using the minimum value of Δa_μ in eq. (1), while the upper bounds are obtained when A^0 is very heavy and using the upper limit for Δa_μ in eq.(1). From these results a quite general and conservative allowed interval can be extracted

$$7.62\times10^{-4}\lesssim\xi^2_{\mu\tau}\lesssim 4.44\times10^{-2}. \tag{7}$$

Furthermore, upper bounds for the product $\xi^2_{\mu\tau}\xi^2_{e\tau}$ are obtained from the expression of the decay width $\Gamma(\mu\to e\gamma)$ in eq. (4) and from the experimental upper limit $\Gamma(\mu\to e\gamma)\leq 3.6\times10^{-30}$ GeV [32]. The most general upper bounds are obtained for A^0 very heavy. The results are shown in table (1) column 2. From this table we infer that quite generally, the upper limit is

$$\xi^2_{e\tau}\xi^2_{\mu\tau}\lesssim 2.24\times10^{-16} \tag{8}$$

Moreover, combining these upper limits with the lower bounds on $\xi^2_{\mu\tau}$ given in the first column of table (1), we find upper limits on $\xi^2_{e\tau}$. The results appear on table (1) third column and the general bound can be written as

$$\xi^2_{e\tau}\lesssim 2.77\times10^{-14}\ . \tag{9}$$

Noteworthy, these constraints predict a strong hierarchy between the mixing elements $\xi_{\mu\tau}$ and $\xi_{e\tau}$ i.e. $|\xi_{e\tau}|<<|\xi_{\mu\tau}|$ and they differ by at least five orders of magnitude.

On the other hand, from eq. (4) we see that the decay widths $\Gamma(\tau\to\mu\gamma)$ and $\Gamma(\tau\to\mu\mu\mu)$ depend on two mixing vertices $\xi^2_{\mu\tau}$, $\xi_{\tau\tau}$ and $\xi^2_{\mu\tau}$, $\xi_{\mu\mu}$ respectively. Then, we can get conservative constraints on the diagonal mixing vertices $\xi_{\tau\tau}$, $\xi_{\mu\mu}$ by using once again the lower bounds on $\xi^2_{\mu\tau}$ obtained from Δa_μ. Since $\Gamma(\tau\to\mu\gamma)$, and $\Gamma(\tau\to\mu\mu\mu)$ are rather complicate functions of $\xi_{\tau\tau}$, and $\xi_{\mu\mu}$ respectively, we present these constraints in the form of contour-plots in the $m_{A^0}-\xi_{\tau\tau}$ plane and the $m_{A^0}-\xi_{\mu\mu}$ plane, figures 1 and 2, each one for the five cases.

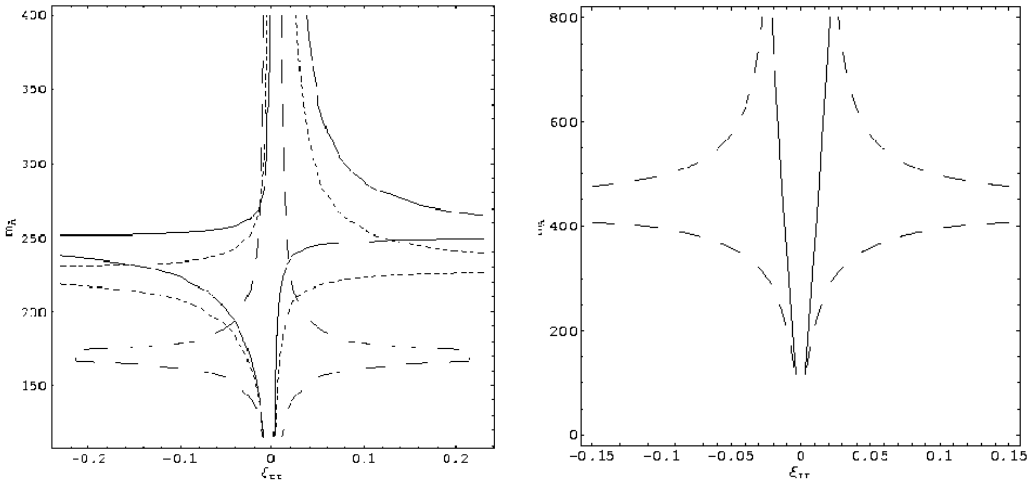

Figure 1: *Contourplots in the $\xi_{\tau\tau} - m_{A^0}$ plane for each of the five cases cited in the text. On left: case 1 corresponds to the long-dashed line, case 4 to the short-dashed line, and case 5 to the solid line. On right: case 2 corresponds to dashed line, and case 3 is solid line.*

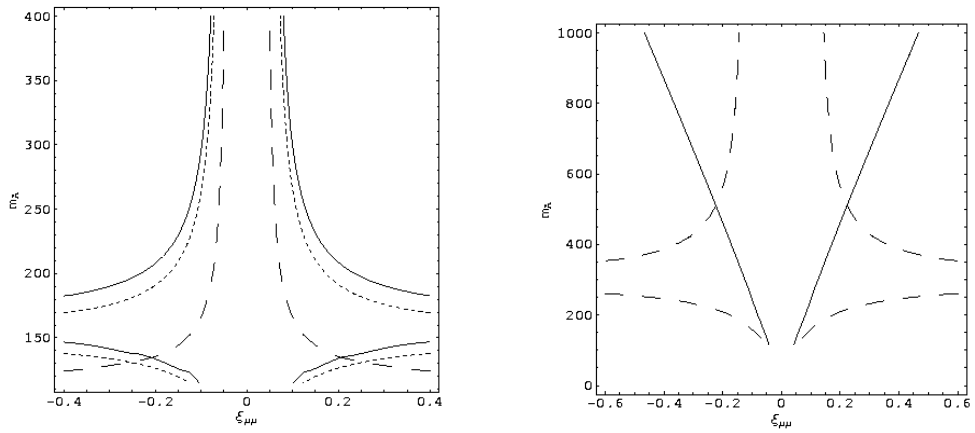

Figure 2: *Contourplots in the $\xi_{\mu\mu} - m_{A^0}$ plane for each of the five cases cited in the text. On left: case 1 corresponds to the long-dashed line, case 4 to the short-dashed line, and case 5 to the solid line. On right: case 2 corresponds to dashed line, and case 3 is solid line.*

We can check that for each contourplot there is a value of m_{A^0} for which $\xi_{\tau\tau}$ or $\xi_{\mu\mu}$ stays unconstrained, and they are shown in tables 2, and 3 respectively. Additionally, the bounds for $\xi_{\tau\tau}$, $\xi_{\mu\mu}$ when m_{A^0} is very large and when $m_{A^0} \approx 115$ GeV are also included in tables 2, 3 respectively. We see that the general constraints for $\xi_{\tau\tau}$ read

$$\begin{aligned} -1.8\times 10^{-2} &\lesssim \xi_{\tau\tau} \lesssim 2.2\times 10^{-2}\,, \\ -1.0\times 10^{-2} &\lesssim \xi_{\tau\tau} \lesssim 1.0\times 10^{-2} \end{aligned} \tag{10}$$

for m_{A^0} very large and for $m_{A^0} \approx 115$ GeV respectively. These constraints are valid for all cases, except for the third case with m_{A^0} very large, since in that scenario $\xi_{\tau\tau}$ remains unconstrained. Now, for $\xi_{\mu\mu}$ the general bounds read

$$\begin{aligned} |\xi_{\mu\mu}| &\lesssim 0.12, \\ |\xi_{\mu\mu}| &\lesssim 0.13 \end{aligned} \tag{11}$$

for m_{A^0} very large and for $m_{A^0} \approx 115$ GeV respectively. Once again these constraints are not valid for the third case when m_{A^0} is very large, but are valid in all the other cases.

The presence of diagonal mixing vertices could play a crucial role in looking for FCNC. At this respect, it is worthwhile to point out that the relative couplings (the quotient between the Yukawa couplings of the new physics and the SM Yukawa couplings) in model type III

$$\begin{aligned} \frac{\left(g_{H^0\overline{f}f}\right)}{\left(g^{SM}_{\phi^0\overline{f}f}\right)} &= \cos\alpha \;-\; \frac{\sqrt{2}M_W\xi_{ff}}{gm_f}\sin\alpha \\ \frac{\left(g_{h^0\overline{f}f}\right)}{\left(g^{SM}_{\phi^0\overline{f}f}\right)} &= -\sin\alpha \;+\; \frac{\sqrt{2}M_W\xi_{ff}}{gm_f}\cos\alpha \end{aligned} \tag{12}$$

are not universal because of the contribution of the factor ξ_{ff}/m_f. As a manner of example, the relative couplings $H^0\tau\overline{\tau}$, $H^0\mu\overline{\mu}$, $H^0e\overline{e}$ are in general different, a deviation from the universal behavior of the relative couplings of the type $Hf\overline{f}$ could be a clear signature of FCNC at the tree level. In the case of the 2HDM type I, all the relative couplings of the form $Hf\overline{f}$ for a certain Higgs are equal. In the model type II, relative couplings of this form are equal for all up-type fermions, and for all down-type fermions. By contrast, in the model type III all relative couplings of the form $Hf\overline{f}$ can be different each other. In addition, in the 2HDM with FCNC the pseudoscalar Higgs couples to a pair of fermions of the same flavor by means of the matrix element ξ_{ff}, different from the case of the 2HDM with no FCNC in which the pseudoscalar couples through the mass of the corresponding fermion.

We can check that our bounds on $\xi_{\tau\tau}$ still permits either a huge suppression or a huge enhancement on the couplings $H\tau\overline{\tau}$ with H being any neutral Higgs. For instance, in the case 5 by using $\xi_{\tau\tau} \simeq 0.01$ the coupling $h^0\tau\overline{\tau}$ vanishes, while

	Values of m_{A^0} for $\xi_{\tau\tau}$ unconstrained	$\xi_{\tau\tau}$ intervals for m_{A^0} very large	$\xi_{\tau\tau}$ intervals for $m_{A^0} \approx 115$ GeV

case 5	$m_{A^0} \approx 163$ GeV	$\lvert\xi_{\mu\mu}\rvert \lesssim 0.061$	$\lvert\xi_{\mu\mu}\rvert \lesssim 0.11$

Table 3: Bounds extracted from the contourplots shown in fig. 2. The first column indicates the values of m_{A^0} for which $\xi_{\mu\mu}$ stays unconstrained for each one of the five cases. The second and third columns show the allowed intervals on $\xi_{\mu\mu}$ when m_{A^0} is very large and when $m_{A^0} \approx 115$ GeV respectively.

using $\xi_{\tau\tau} \simeq 0.1$, we see that the contribution coming from the term proportional to $\xi_{\tau\tau}$, is about 10 times larger in magnitude than the contribution coming from the term proportional to the tau mass. In the case 5 both values $\xi_{\tau\tau} = 0.01$ and $\xi_{\tau\tau} = 0.1$ are allowed at least for m_{A^0} around 250 GeV, as it is shown in fig. (1). However, for a very light ($m_{A^0} \approx 115$ GeV), or a very heavy pseudoscalar Higgs boson, constraints on $\xi_{\tau\tau}$ are considerably stronger in all cases, see table 2. Similarly, strong or weak couplings of $H^0\tau\tau$ and/or $A^0\tau\overline{\tau}$ are still allowed. Of course, the same pattern is accomplished by the bounds for $\xi_{\mu\mu}$ since they are weaker than the constraints on $\xi_{\tau\tau}$.

Based on the bounds obtained above, we are able to estimate upper limits for some leptonic decays by using the expressions (4), (5), and (6). We shall assume that $|\xi_{\tau\tau}| \approx |\xi_{ee}| \lesssim 0.1$, from this assumption we can obtain the following upper bounds

$$\begin{aligned} \Gamma(\tau \to e\gamma) &\lesssim 1.5 \times 10^{-27}, \\ \Gamma(\tau \to eee) &\lesssim 5 \times 10^{-29}. \end{aligned} \tag{13}$$

If we compare with the current experimental upper bounds $\Gamma(\tau \to e\gamma) \leq 6.12 \times 10^{-18}$, $\Gamma(\tau \to eee) \leq 6.57 \times 10^{-18}$ [32], we see that these decays are predicted to be very far from the reach of next generation experiments in the context of the 2HDM type III, unless that $\xi_{\tau\tau}$,and/or ξ_{ee} acquire unexpectedly large values.

3 Concluding remarks

We calculated some constraints on lepton flavor violating vertices in the framework of the 2HDM type III, by assuming $m_{h^0} \approx 115GeV$ and $m_{A^0} \gtrsim m_{h^0}$. Since the most recent estimations of Δa_μ, still provides an important window for new Physics, we obtain from it lower and upper bounds on the mixing vertex $\xi_{\mu\tau}$ at 95% C.L. Specifically, an allowed interval of $7.62 \times 10^{-4} \lesssim \xi^2_{\mu\tau} \lesssim 4.44 \times 10^{-2}$ was found in a quite wide region of parameters. Of course, we should realize that both SM test and experimental measurements of a_μ are still being scrutinized and current results are not definitive at all. However, if not severe changes occur in forthcoming experiments and SM estimations, these constraints could continue being valid at least at a lower confidence level. Future improvements on both estimations should elucidate this point.

Based on these constraints, and on the leptonic decays $\mu \to e\gamma$, $\tau \to \mu\gamma$, and $\tau \to \mu\mu\mu$ we got the following conservative and quite general bounds on LFV vertices

$$\xi^2_{e\tau} \lesssim 2.77 \times 10^{-14}. \tag{14}$$

For $\xi_{\tau\tau}$ we find

$$\begin{aligned} -1.8 \times 10^{-2} &\lesssim \xi_{\tau\tau} \lesssim 2.2 \times 10^{-2}, \\ |\xi_{\tau\tau}| &\lesssim 1.0 \times 10^{-2} \end{aligned} \tag{15}$$

for m_{A^0} very large and for $m_{A^0} \approx 115$ GeV respectively. For $|\xi_{\mu\mu}|$ we find

$$\begin{aligned} |\xi_{\mu\mu}| &\lesssim 0.13, \\ |\xi_{\mu\mu}| &\lesssim 0.15 \end{aligned} \tag{16}$$

for m_{A^0} very large and for $m_{A^0} \approx 115$ GeV respectively. Notwithstanding, those bounds on $\xi_{\tau\tau}$ and $\xi_{\mu\mu}$ are considerably relaxed for certain specific values of m_{A^0}. In that case, the room available for them is such that they permit either a strong enhancement or a strong suppression of the couplings $H\tau\overline{\tau}$ and/or $H\mu\overline{\mu}$ for any neutral Higgs boson. Additionally, according to these constraints we find that $|\xi_{\mu\tau}|$ is at least five orders of magnitude larger than $|\xi_{e\tau}|$ revealing a strong hierarchy between them.

Furthermore, we estimate upper limits on the decay widths $\Gamma(\tau \to e\gamma)$, and $\Gamma(\tau \to eee)$, finding that they are basically hopeless to look for LFV processes in near future experiments, at least in the framework of the 2HDM type III with heavy Higgs bosons.
